In a large number of engineering applications it is advantageous to look into the flow of fluids, for example, in order to find out the critical point at which a flow starts collapsing. Such critical points are often located in a region, that is, the pressure of a flow just outside the critical point being lower than the pressure of the fluid just inside the critical point. A critical point is thus placed in the vicinity of the marginal stable state of the flow. Knowing the pressure at the critical point is advantageous for the user of such a fluid flow. Moreover, it is also advantageous in the petroleum industry to know the pressure of the fluids at or near the well heads because more accurate and reliable pressure measurements will then be obtained, which will lead to more accurate results in the reservoir analysis. Hydraulic jumps are the norm in the petroleum production industry and pressure profiles near the well heads are very complex. The critical point of a flow can be thought of as the place in the flow at which the flow suddenly collapses from a higher to a lower density. This critical point is also referred to as an "end point" or "marginal state". Fluid from the lower density region may be either in the form of a very high phase velocity, or in the form of a very thin shear
