[The molecular genetic approach to the diagnosis of the recessive form of X-linked hypophosphatemic rickets]. Hypophosphatemic rickets (HR) is the most frequent cause of rickets. It is caused by mutations in the PHEX gene, which has been identified on Xp22.3. The goal of the study was to establish a molecular genetic assay for the identification of mutations in PHEX gene in families with HR. Genomic DNA was isolated from peripheral blood leukocytes. The diagnosis of X-linked hypophosphatemic rickets was made on the basis of clinical, biochemical, and histopathological criteria of disease and X-chromosome inactivation studies. Mutation analysis was performed by denaturing high-resolution-polymerase chain reaction (PCR) and single strand conformation polymorphism (SSCP) analysis of all exons of the PHEX gene. We analyzed mutations in 10 patients from 7 families and, in accordance with the results of the X-chromosome inactivation test, detected heterozygous PHEX mutations in 7 families. In 1 of these families a mutation was found in 4 members of the kindred, which had never been informed of the possibility of HR. Analysis of molecular genetic testing of PHEX mutations in patients with HR is of great importance for clinical practice and should be performed in all affected families. 4.0.0

Click to place the area where you want to erase the old area. Most areas you want to remove are marked with a border line around the area of overlap. This lets you know where you are most likely to clone from. You should keep your Clone Stamp close to the area you want to erase. If you stray too far, then you might accidentally erase a part of the image or even the image you are working on. After you click the mouse, the area you have selected is copied to another location. It will look like a thin red box surrounding the area you had selected. The screen will look like this: The Clone Stamp is active If you have pixel the area you are copying, then it will be a soft, pastel blue color instead of a hard black outline.
