I'm using AWS Lambda function to store and retrieve documents from S3 bucket. I want to increase the size of the data storage to several terabytes, but I'm not sure how to define the physical size in the application. All the documentation says that the physical size is calculated based on the size of the object in the container and the max size of the container, but I'm not clear what the container size will be. Does anyone know if there is a way to define the object size in the deployment package of the Lambda function? A: While I can't answer the question in terms of sizes, I can answer it in terms of functionality. As far as I understand, you are willing to pay the cost of a PSS instance in order to use it. There is a much more cost effective way to store terabytes of data and get the same functionality. Use Amazon EBS. As far as I know, it's the only "native" solution. I've used it for terabytes before. The cost is higher (a few hundred dollars per month), but it is stable. It doesn't require PSS instances. Courses and Academic Programs This chart on the seven types of nursing programs illustrates a spectrum of various baccalaureate, graduate-preparation, and continuing-education programs. Some of the programs are designed for health-care professionals, while other programs are for individuals with no health-care career objective. c6a93da74d
